Tutorial docs

- Not comprehensive
- Focus on the user
- Read beginning to end

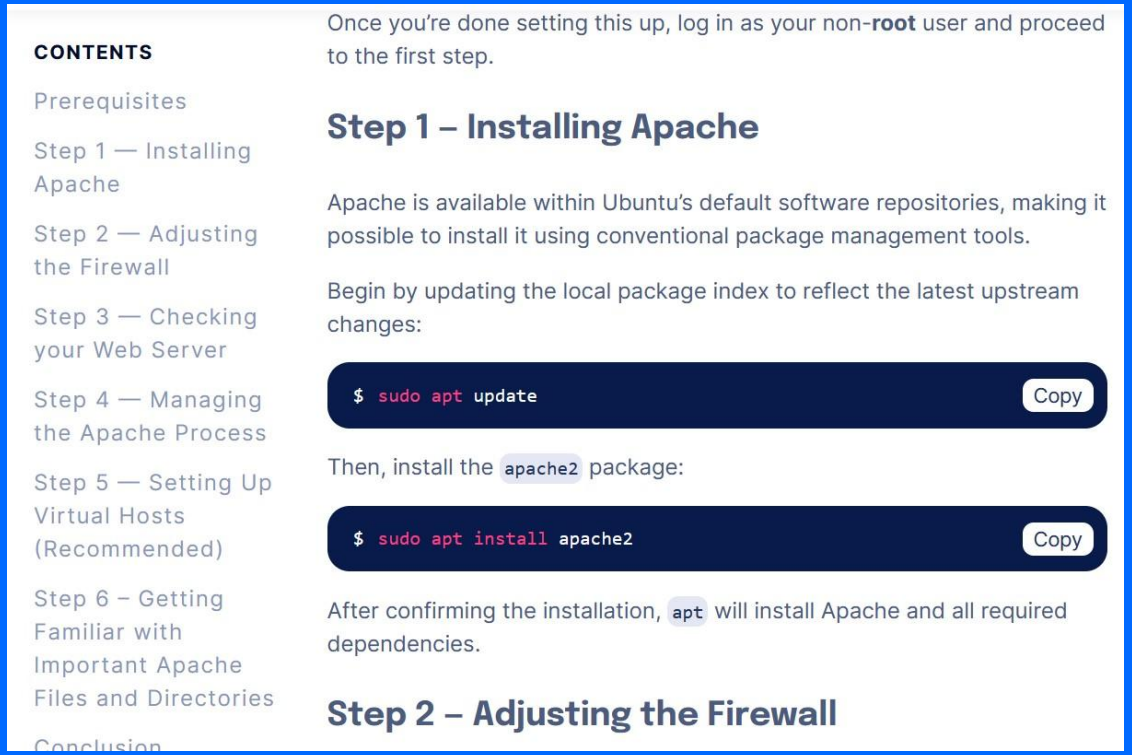
Tutorial docs

Tutorials

How-tos

Walkthroughs

Use cases



CONTENTS

Prerequisites

Step 1 — Installing Apache

Step 2 — Adjusting the Firewall

Step 3 — Checking your Web Server

Step 4 — Managing the Apache Process

Step 5 — Setting Up Virtual Hosts (Recommended)

Step 6 – Getting Familiar with Important Apache Files and Directories

Conclusion

Once you're done setting this up, log in as your non-**root** user and proceed to the first step.

Step 1 – Installing Apache

Apache is available within Ubuntu's default software repositories, making it possible to install it using conventional package management tools.

Begin by updating the local package index to reflect the latest upstream changes:

```
$ sudo apt update
```
Copy

Then, install the `apache2` package:

```
$ sudo apt install apache2
```
Copy

After confirming the installation, `apt` will install Apache and all required dependencies.

Step 2 – Adjusting the Firewall

References are Nouns

They tell you what something IS

When You Organize by Noun

File menu

New - Opens a new document. If you use the keyboard combination indicated on the right a blank document opens immediately. Selecting the New menu item with your cursor gives the opportunity to open a large number of types of documents.

Open - Opens a previously saved document.

Close - Closes the active document but does not quit the application.

Save - Saves the active document with its current file name, location and format.

Save As - Saves by opening a window which gives the opportunity to change the file name, location or format.

Page Setup - Sets margins, paper size, orientation and other layout options.

Print Preview - Shows how the file will look when you print it.

Print - Prints the active file, also gives the opportunity to change print options

Exit - Closes Microsoft Word.

Writing at the step level

The installation process will ask you about importing a GPG key. Confirm it so the installation can complete.

Now that you have Certbot installed, let's run it to get a certificate.

Step 2 – Confirming Nginx's Configuration

Certbot needs to be able to find the correct `server` block in your Nginx configuration for it to be able to automatically configure SSL. Specifically, it does this by looking for a `server_name` directive that matches the domain you request a certificate for.

Writing at the paragraph level

Writing at the paragraph level

- Keep it concise

To add the Rocky Linux 9 EPEL repository, run the following command:

```
$ sudo dnf install epel-release
```

Copy

When asked to confirm the installation, type and enter `y`.

Now that you have access to the extra repository, install all of the required packages:

```
$ sudo dnf install certbot python3-certbot-nginx
```

Copy

This will install Certbot itself and the Nginx plugin for Certbot, which is needed to run the program.

The installation process will ask you about importing a GPG key. Confirm it so the installation can complete.

Now that you have Certbot installed, let's run it to get a certificate.
